The lights on the throttle are powered by a wire thats connected more or less direct to the battery. Everything can work without any power to those lights, but if theyre not on, it implies that the battery isnt connected to the controller. Heres a wiring schematic. Its the yellow wire to the throttle that carries the battery voltage for the LEDs. The red green and black wires are for the throttle and theyre completely independent. The twowire connector red and black that the yellow wire is connected to should have battery voltage on it 29v fully charged. If it hasnt, theres something wrong with the battery connections The lights on the throttle are powered by a wire thats connected more or less direct to the battery. If it hasnt, theres something wrong with the battery connections You know it needs to be connected to a battery positive for the controller to be activated. When you connect it, check that the voltage doesnt drop down again. The battery docking design is poor, and allows for a lot of vertical movement of the battery whilst riding. This causes the contacts of the battery to open up, creating electrical resistance at the point of contact with the docking prongs. Im not saying this is definitely the problem, but I had battery contact problems when I owned one. Cleaning the contacts with a cotton bud dipped in electrical cleaner, and squeezing the battery contacts slightly inwards, solved the issue of thinking my battery had died.
